

MUTATION TESTING AT A GLANCE

What is Mutation Testing?

A type of software testing where parts of the code are changed, or “mutated”, to see if your unit tests can detect the errors and fail.

Team Member Benefits

Performing mutation testing will help team members identify potential production bugs and errors sooner, leading to fewer eRocs.

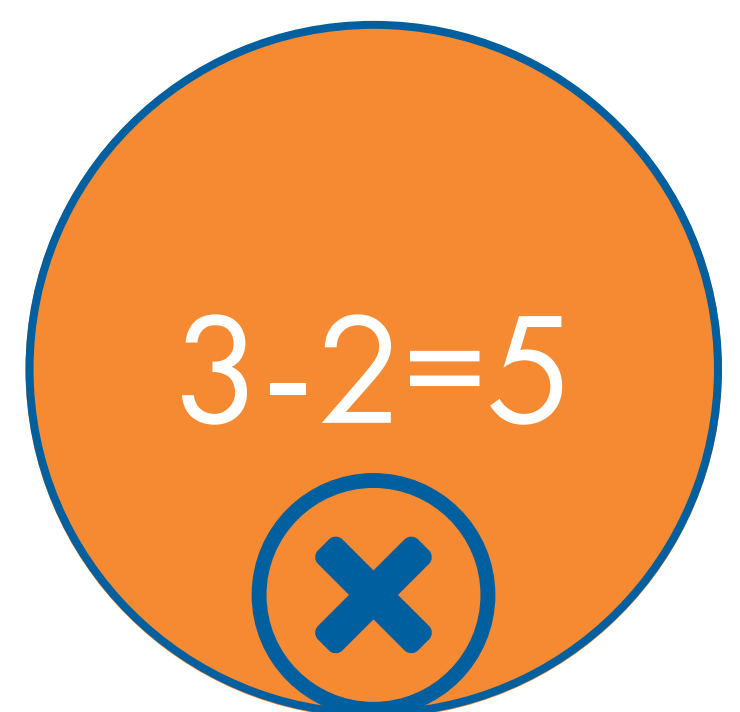

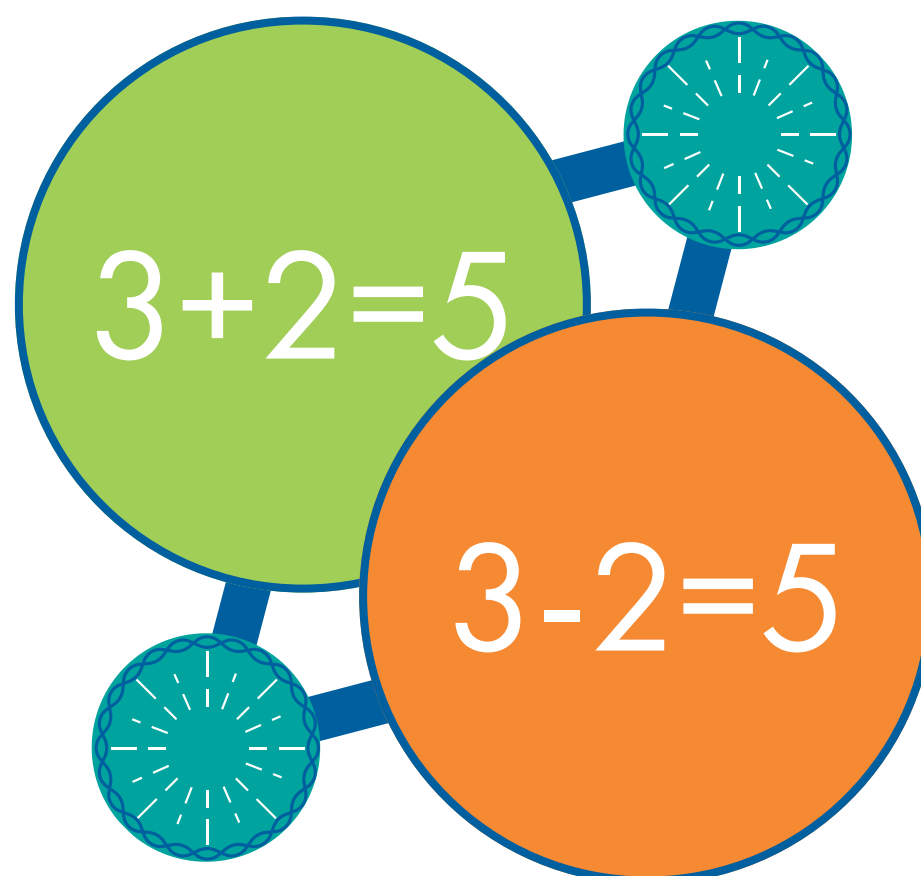

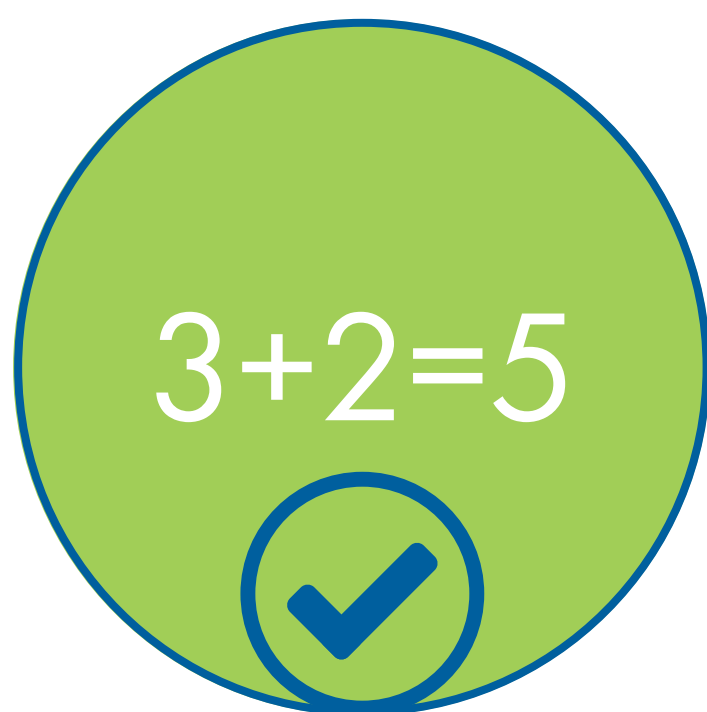

UWM Benefits

By introducing intentional faults to the code, team members will have to write higher quality unit test that can catch these faults.

How Does It Work?

Mutation testing will copy and alter your code by introducing bugs prior to running any unit tests. Ideally the unit tests will fail as a result of the mutations.

MUTATION TESTING IN ACTION

First, your code should **SATISFY** the unit test designed for it.

Then, the mutation test will **COPY** and **MUTATE** your code.

Your unit tests **SHOULD FAIL** as a result of the mutations. The more mutations your unit test catches, the better the test is!
